The Boulder Content of Midlatitude Ground Ice on Mars C. Singh¹ (christina@arizona.edu), S. Byrne¹, M. P. Golombek², M. R. Trautman², C. M. Dundas³, M. A.Vona², N. R. Williams² **PLANETARY LAB** ¹Lunar and Planetary Laboratory, The University of Arizona, ²Jet Propulsion Laboratory, California Institute of Technology; ³U.S. Geological Survey By quantifying the size-frequency distributions of boulders on ice sheets and around craters, we can understand the origin of boulder emplacement, which can inform us about the climate and habitability of Mars over time and provide insight for future in situ missions. Observations Hypotheses **Sublimation** Boulders on <u>thermokarsts</u> <u>icy terrain</u> 3. Seasonal frosts Exposed ice 1. Impacts 2. Preliminary Results

> All surveyed boulder cumulative fractional areas (CFA) show scallops contain more boulders than the

Other factors to consider

- > Non-uniform distribution of boulders within ice

Future Work

Survey icy landforms (scallops, icy scarps, boulder halos) globally for boulder-ice content Analyze the morphology of:

#2613

surrounding plains (ratios ≥ 1) > Trapping of fine-grained material (either > Most boulder abundances analyzed are low (few rocky) from a sublimation lag or an exogenous source) within scallop pits plains) Variations in CFA ratios inform us about boulder-ice Longitudinal variations in icy-mantle

density, porosity, and composition

• Features (slopes, circularity, layering, depths, uniformity)

 Local area (specific landforms, regional influences, or triggers)
